## * Quantile Transformer:

It is a data preprocessing technique where it transforms features of datasets distribution into a desired distribution, usually uniform or normal, by mapping values according to their percentile ranks.

It is useful for handling skewed data and reducing the influence of outliers.

$$X_{new} = G^{-1}(F(x))$$

X = original value
F(x) = Cumulative percentage percentile of original value
$G^{-1}$ = Inverse cumulative distribution function of the target distribution
$X_{new}$ = Transformed value

Where to use? → highly skewed or extreme outliers

less suitable for linear models.

model suitable: KNN, SVM, Nueral network
